## <sup>6</sup> Summary

<sup>7</sup> The movement of charge and energy is a fundamental process in materials science, underpinning <sup>8</sup> technologies such as solar cells, light-emitting diodes, batteries, and electronics. Transport <sup>9</sup> is well understood in both highly ordered materials (band conduction) and highly disordered <sup>10</sup> ones (hopping conduction). However, in moderately disordered materials—including many <sup>11</sup> organic semiconductors—transport lies in the intermediate transport regime between these <sup>12</sup> well-understood extremes. Accurately modelling intermediate-regime conduction is difficult <sup>13</sup> because describing wavefunction delocalisation requires a fully quantum-mechanical treatment, <sup>14</sup> which is challenging in disordered materials that lack periodicity. We describe delocalised <sup>15</sup> kinetic Monte Carlo (dKMC), the first theoretical approach to treat, in three dimensions, all the <sup>16</sup> processes crucial in organic semiconductors: disorder, delocalisation, and polaron formation. As <sup>17</sup> a result, it can treat the intermediate transport regime between band and hopping conduction. <sup>18</sup> dKMC reveals that the fundamental physics of transport in moderately disordered materials is <sup>19</sup> that of charges and excitons hopping between partially delocalised electronic states. In this <sup>20</sup> work, we release the dKMC.jl package, which contains modules for simulating the fundamental <sup>21</sup> processes of charge and exciton transport as well as charge separation and generation.

**Figure 1:** Figure 1: While transport mechanisms are well understood in the extremes, coherent band conduction through extended states and incoherent hopping through localised states, they remain poorly understood in the intermediate regime where many organic semiconductors lie. Figure adapted with permission from [[@Balzer2021](#)].

## <sup>22</sup> Statement of need

<sup>23</sup> The need for dKMC is demonstrated by its ability to solve two important problems.

<sup>24</sup> First, dKMC is the first computational technique that is able to include all of the processes crucial  
<sup>25</sup> in organic semiconductors while remaining computationally tractable enough to treat realistic,  
<sup>26</sup> three-dimensional systems on mesoscopic time and length scales[@Balzer2021]. Before dKMC,  
<sup>27</sup> the difficulty in modelling transport in the intermediate regime had prevented the development  
<sup>28</sup> of such a theory. Instead, prior approaches either needed to exclude one of the key ingredients  
<sup>29</sup> (disorder, delocalisation, and polaron formation), which could lead to inaccurate results, or  
<sup>30</sup> included them all but restricted the application to smaller systems (dimension, time, and length  
<sup>31</sup> scales). dKMC solves these problems, striking a balance between the level of approximation and  
<sup>32</sup> the size of the system it can simulate. Therefore, dKMC provides a simulation tool that can  
<sup>33</sup> both accurately and efficiently simulate fundamental transport processes involving partially  
<sup>34</sup> delocalised carriers.

<sup>35</sup> Second, dKMC explains the often confusing behaviour of organic electronics, including organic  
<sup>36</sup> photovoltaics (OPVs). Most models of transport in disordered organic semiconductors assume  
<sup>37</sup> hopping transport, where charge carriers or excitons are localised onto individual molecules  
<sup>38</sup> and move via thermally assisted hops from one molecule to the next. However, hopping  
<sup>39</sup> transport fails to explain how charges and excitons move as fast as they do, or how charges in  
<sup>40</sup> OPVs overcome their strong Coulomb attraction and separate from CT states as efficiently  
<sup>41</sup> as they do, or how charges are generated so efficiently even in OPV devices with little  
<sup>42</sup> to no energetic offsets. Hopping transport fails because, in many organic semiconductors,  
<sup>43</sup> the charges and excitons remain delocalised across multiple molecules. By going beyond  
<sup>44</sup> hopping, dKMC reveals that delocalisation improves each of the four fundamental transport  
<sup>45</sup> processes in OPVs: charge transport[@Balzer2021], exciton transport[@Balzer2023], charge  
<sup>46</sup> separation[@Balzer2022], and charge generation[@Balzer2024]. Delocalisation improves all  
<sup>47</sup> of these important transport processes in essentially the same way, by enabling carriers to hop  
<sup>48</sup> further and faster, explaining the failure of classical theories. Therefore, dKMC is a tool for  
<sup>49</sup> explaining the otherwise unpredictable behaviour observed in devices.

<sup>50</sup> dKMC was developed for organic semiconductors, but it can be more generally applied to other  
<sup>51</sup> materials that lie in the intermediate regime. In particular, the first application of dKMC was to  
<sup>52</sup> OPVs and therefore the package contains a module for each of the four fundamental processes in  
<sup>53</sup> OPVs: charge transport, exciton transport, charge separation, and charge generation. However,  
<sup>54</sup> the transport modules can be more generally applied to organic semiconductor materials used  
<sup>55</sup> in other devices, such as organic light-emitting diodes or organic field-effect transistors.

## <sup>56</sup> Acknowledgements

<sup>57</sup> We were supported by the Westpac Scholars Trust (Research Fellowship and Future Leaders  
<sup>58</sup> Scholarship), by the Australian Research Council (DP220103584), by the Australian Government  
<sup>59</sup> Research Training Program, and by the University of Sydney Nano Institute Grand Challenge  
<sup>60</sup> Computational Materials Discovery. We were also supported by computational resources from  
<sup>61</sup> the National Computational Infrastructure (Gadi) and by the University of Sydney Informatics
